Purpose: Today, depending on topic, goal and budget, all kinds of sampling methods are being used, in order to collect consumer data for research in the wine business. However, it is questionable which survey method is able to generate data that does represent the entire population. Using identical questions administered through face-to-face, telephone and online interviews, this is the first study to investigate the effects of survey mode in wine consumer research.

Design: A representative face-to-face survey with 2,000 respondents and a telephone survey with 1,000 respondents were compared with two online surveys, one based on quota sampling (2,000) and the other on snowball sampling (3,000).

Findings: Due to the sampling method, three of the surveys were representative of the socio-demographic structure of the German population in terms of six demographic variables which were selected for the quota sampling. The online survey based on the snowball sample had large biases concerning representativeness. As for the behavioural characteristics, the face-to-face data delivered the best results, followed by the telephone interviews and finally, by the online quota survey.

Practical implications: Face-to-face surveys still deliver the most representative results. Telephone surveys may provide a good alternative, but we would advise use of a larger sample. The online quota survey needs much more correction or maybe some behavioural variables, while in the case of snowball sampling, one should relinquish the idea of representativeness.

Key words: Face-to-Face, Telephone, Online, Survey mode, Representativeness

1. INTRODUCTION

From the 1940s to the 1970s, mail and face-to-face surveys were the main modes of data collection (Lyberg and Kasprzyk, 1991). However, the increasing rates of telephone coverage, the low cost of telephone surveys relative to face-to-face, the speed with which telephone surveys can be conducted, as well as the quality of the data produced have all contributed to the global success of telephone surveys. Telephone interviewing of samples generated by random digit dialling became an especially popular method (Dillman, 2000). Since the 1990s, when Internet surveys were introduced, they began to threaten the dominance of telephone surveys because of their advantages in terms of speed and costs. Internet surveys appeared as a promising alternative; nevertheless, there are still problems with the coverage and, as a result of this, with the representativeness of online surveys (Couper, 2011). Therefore, researchers, today, are often hesitant to do Internet-based data collection when the goal is to yield a representative national sample (Chang and Krosnick, 2009).

In wine consumer research, all kinds of sampling methods have been in use, depending on the topic, goal and budget of the survey. Traditional methods such as face-to-face, telephone or national mail surveys have already been proven, and the results of these kinds of surveys can be published as representative of the population. However, as indicated in several studies quoted below, it is questionable whether online surveys do represent the entire population.

Aquilino (1994), Greenfield (1999) as well as Midanik and Greenfield (2003) already dealt with the question of alcohol in their comparison studies of face-to-face and telephone surveys. However, they did not investigate only wine consumers; rather, they tested these two modes in terms of sensitive questions such as those relating to alcoholism. As far as we know, there have been no studies investigating various sampling methods in wine consumer research, although it would be necessary in order to analyse the effectiveness of these modes. This study therefore focuses on comparing four different sampling methods (face-to-face, telephone and two online methods) with identical questionnaires, used when interviewing wine consumers. Its goal is to analyse the effect of each mode, including what and how large are the differences in the behavioural and demographic profiles of the respondents across these modes. Outcomes of this study should help in the mode choice and in the interpretation of results of surveys administered by face-to-face, telephone or online methods.

We begin below by outlining past comparison studies of modes and by comparing face-to-face, telephone and Internet surveys with each other in terms of advantages and disadvantages. This is followed by a description of the national study and by the results of the analysis, which has the goal of highlighting the differences between the selected modes. Finally, in the conclusion, we give an overview of the most important findings and discuss managerial implications of further research.

2. LITERATURE OVERVIEW

The current literature mainly focuses on analysing online and face-to-face or telephone surveys in terms of response rate, sensitive questions, social desirability, or 'don't know' responses. There is only a small amount of research that offers comparisons concerning the quality and representativeness of these different survey modes (Bracken et al., 2008). First, we briefly outline the advantages and disadvantages of the chosen sampling methods and then we continue with the literature overview.

2.1 Advantages and disadvantages

Face-to-face surveys have several key strengths. These surveys are clearly structured, flexible and adaptable. They are based on personal interaction and can be controlled within the survey environment. Physical stimuli can be used, and there is the capability to observe the respondents. On the other hand, there are also some disadvantages, such as interviewer bias,

high cost per respondent, geographical limitations and time pressure on the respondents (Holbrook et al., 2003; Alreck and Settle, 2004).

During the past sixty years, the use of *telephones* for the collection of survey data has been transformed from a rarely used and often criticised method into a dominant mode of data collection all over the world. Current statistics show that the telephone survey is still one of the most important survey modes (AMD, 2012), although the trend is falling. The possibility of random digital dialling (RDD), good geographical coverage, personal interaction and lower cost compared to face-to-face surveys contributes to the advantages of telephone surveys. Major potential disadvantages include interviewer bias, lower response rate and the inability to use visual help (Goldstein and Jennings, 2002; Peterson et al., 2003).

Online surveys have a number of strengths such as cost and speed; they are visual, interactive, and flexible; they do not require interviewers to be present and busy people – often educated and well-off – who systematically ignore taking part in a telephone survey are willing to answer questions posted on their computer screens (Kellner, 2004; Duffy et al., 2005). Nevertheless, Couper (2011) noted that relying on such modes, which require initiative from respondents, will likely lead to selective samples, raising concerns about nonresponse bias. The samples being used for large national and international face-to-face and telephone surveys are considered representative for the general population, while online samples are currently regarded as being representative of population subgroups only (Hoogendorn and Daalmans, 2009).

At the beginning of the twenty-first century experts expected that the majority of survey research would be done online (Schonlau et al., 2001; Evans and Mathur, 2005). In the year 2000, the proportion of online surveys in Germany was only 3% of all surveys; at present, it is 36% (AMD, 2012). In spite of the continuously growing number of Internet users, the basic drawback – the lack of representativeness of the entire population – still has not disappeared. With 51.5 million of its people online, Internet access in Germany (Walker, 2012) is still heavily distorted by age, education and gender (Blasius and Brandt, 2010). The current practice for making the sample representative is to weight variables in respect of socio-demographic characteristics as well as different attitudes (Loosveldt and Sonck, 2008; Lee and Valliant, 2009). The above-mentioned bias of online samples may cause a weighting factor of 100 (Vehovar et al., 1999; Faas and Schoen, 2006); however, Bandilla et al. (2003) already reported that weighting variables at a level greater than five is seen as very problematic and not very helpful.

Web-panel surveys offer an alternative sampling method; however even this mode has problems with representativeness (see Duffy et al., 2005; Taylor et al., 2009). In Germany, for example, 4.7% of all Internet users are registered in any kind of Web panel. These are so-called heavy users who use the Internet several times a day. The response rate of these panels is approximately 20%, so we can conclude that 1% of the Internet users in Germany can be reached by Web-panel surveys (Liljeberg and Krambeer, 2011).

The online survey is still developing, and new techniques such as Skype videophone surveys, social media surveys and mobile device surveys with the help of smartphones open new possibilities.

2.2 Face-to-face versus telephone

Some of the earliest results of comparing face-to-face interviews and telephone surveys were reported by Hochstim (1967), Roger (1976) and Groves (1979). In these studies, general questions concerning use of scales in telephone interviews and popularity of these survey modes were investigated. Groves (1979) found that respondents expressed more discomfort about discussing sensitive topics over the telephone than face to face. The interviewers reported that most respondents said they would have preferred to be interviewed face to face rather than by telephone.

Herzog and Rodgers (1988) compared the two modes of data collection across two age levels (under 60 years/60 years of age and older). They found that the older group did not exhibit larger mode differences on response distribution than the younger respondents. Wilson et al. (1998) underlined, in their study, the importance of training and supervising the telephone interviewers as an important factor which can influence the quality of telephone surveys.

Ellis and Krosnick (1999), who compared ten different studies investigating the difference between personal and telephone interviews, came to the conclusion that telephone surveys conducted in the 1970s and 1980s in the USA contained a greater proportion of the well-educated and the wealthy. This was partly because of the lower telephone coverage and partly because of the higher refusal rate of lower-educated and lower-income groups. However, ten years later Maguire (2009) reported just the opposite. She analysed 350 observations and examined mode effects in contingent valuation research. In this study, subjects in the telephone survey were younger, less educated and had lower per capita income. This huge difference shows the incredible development of telephone coverage within ten years.

Some studies investigated the use of telephone versus face-to-face interviewing to gather data on the consumption of alcohol and drugs, as well. Aquilino (1992, 1994) compared a face-to-face survey with 2000 respondents and a telephone interview with 1,000 respondents. His results showed that the telephone survey achieved response rates lower than the personal interview. Lack of response to sensitive drug questions was lower by phone than in the face-to-face study. The author reported that the exclusion of households without telephones might have caused a bias leading to underestimation of alcohol and drug use among the minority population. Based on the results of Aquilino's study, Greenfield et al. (2000) conducted a comparative study, again using the two interview modes: 2,000 face-to-face versus 2,000 telephone surveys. This study did not reveal any significant differences in overall national estimates of several key drinking variables, based on interview mode. Also, Midanik and Greenfield (2003), who compared a subsample of a bigger national alcohol survey, came to the conclusion that there are no significant differences between face-to-face and telephone interview modes.

2.3 Telephone versus online

Fricker et al. (2005) carried out an experiment that compared telephone and Internet versions of a questionnaire. They recruited the respondents via telephone and those with Internet access were randomly assigned to complete either a Web or a telephone version of the questionnaire. Therefore, this study was not a classical comparison, but rather a test of questioning technique. The results showed that the authors got a much higher overall response rate in the telephone interviews. Both samples of Web users did a poor job of representing the overall population of adults.

Taylor et al. (2009) conducted a national survey about the air quality in national parks and compared, in its framework, the effects of modes such as telephone and Web surveys. These results showed again that the response rate was much lower for the Web survey than for the telephone survey. Weighting the respondents could not eliminate significant demographic and behavioural differences across the modes. In addition, social desirability was detected by the telephone surveys, since these respondents demonstrated willingness to pay significantly higher rates than those involved in the online research.

In a study conducted by Kreuter et al. (2009), it was reported that Internet-based surveys increased the reporting on sensitive information, compared to computer-assisted telephone interview (CATI). In their survey modes comparison, Back et al. (2009) came to the conclusion that Web surveys have a great bias relative to conventional RDD telephone surveys and for that reason, they are not yet able to replace the telephone surveys.

A probability and a nonprobability sample administered by the Internet and a RDD telephone interview were compared in a study by Chang and Krosnick (2009). It turned out that the

probability sample was more representative than the nonprobability sample, in terms of demographic variables. The nonprobability sample was biased by high engagement and knowledge about the survey's topic. In addition, the telephone survey responses manifested more social desirability response bias than the Internet survey. These results correlate strongly with the results of Yeager et al. (2011), who set up a similar study which, however, involved seven non-probability samples of Internet surveys to be compared with probability samples of telephone and Internet surveys.

In a study conducted in Germany by Liljeberg and Krambeer (2012), telephone and online surveys on different topics were compared. The authors came to the conclusion that the result of an online study cannot be labelled as representative, not even with a weighting of demographic variables.

2.4 Face-to-face versus online

Newman et al. (2002) assessed the differential effects between face-to-face interviews and computer-assisted self-interviewing (CASI). They investigated 700 participants of a drug program for each interviewing mode, although in this study, it was the interviewer effect and not the representativeness that was analysed. In the case of sensitive questions involving self-reports on drug use or other stigmatised behaviours, the response rate in the CASI survey was higher. The positive effect of abstinence of interviewers when asking sensitive questions was also reported in the study by Taylor et al. (2005).

Unlike face-to-face surveys, online studies are most often conducted among respondents from a panel. In his study, Terhanian (2003) summarised the following problems which can lead to a bias in surveys with respondents from an online panel: one can reach only those who are online; one can reach only those who agree to become part of a panel; not all those who are invited respond; and, those who sign up for online panels are rather young and male.

Duffy et al. (2005) conducted a comparative study with face-to-face and online surveys; for the latter an online panel was used. In this study, raw and weighted data were compared. They came to the conclusion that online research using panel members appears to attract a more knowledgeable, viewpoint-orientated sample than face-to-face surveys. However, respondents in face-to-face interviews are more susceptible to social desirability bias because of the interviewer's presence (Duffy et al., 2005). Another comparison was carried out by Heerwegh and Loosveldt (2008), who confirmed the hypotheses that Web surveys elicited more 'don't know' responses, more nondifferentiation on rating scales and a higher item nonresponse rate. Quite contrary to the abovementioned results, Lindhjem and Navrud (2011) argued that in their study the 'don't know' response rate was similar in both modes. Maybe the difference in the results was affected by the varied sample sizes and by the topic variation. Lindhjem and Navrud (2011) used a 300 (face-to-face) and a 380 (online) sample, which are small sample sizes, compared to the other studies. In addition they dealt with the variable *willingness to pay for biodiversity protection plans*.

Blasius and Brandt (2010) conducted a stratified online study with 1,300 cases in Germany and compared it with a representative face-to-face survey. Although both samples were equivalent in terms of age, gender and education, it turned out that the online sample was not representative of the entire population.

3. METHOD

In order to test for effects of research modes in wine consumer research, one face-to-face, one telephone and two online surveys were administered to the German population aged 16 or older, in national surveys consisting of 1000, 2000 and 3000 respondents. The data collection was conducted by professional international surveys firms. The firms got identical written introductions and were asked to provide 1,000 and 2,000 completed surveys with a census-representative sample, except for one of the Internet surveys, which was based on a snowball

sampling method. The face-to-face survey, the telephone survey and one of the online surveys were conducted using quota sampling based on German micro-census data, which is a 1% probability sample of the entire population conducted by the Federal Statistical Office (Blasius and Brandt, 2010). For the quota sampling, demographic variables were used, such as gender, age, household size, city size, occupation and state. The other online survey was based on snowball sampling.

The representative face-to-face and telephone surveys were conducted in December 2011 and 2012¹. The random sampling of 2,000 respondents for the face-to-face survey and 1,000 for the telephone survey is representative for the socio-demographic structure of the population from the age of 16 upwards in Germany. These surveys were carried out on the basis of a quota sample using personal as well as telephone interviews which took place in the households of the interviewees. The online panel, from which the sample of the first online survey was drawn, included 200,000 individuals, whose demographic characteristics were known by registration. This survey was conducted in December 2012, with a sample size of 2,000 panellists. The second online survey with snowball sampling was accomplished in November and December 2012. In this case, approximately 100 students of the Geisenheim University studying viticulture and oenology as well as the international wine business were asked to send to their relatives and friends an e-mail with a link to the survey. Furthermore, those who had already filled out the questionnaire were asked to forward the e-mail with the survey link to their relatives and friends. In this way there were 3,000 respondents who answered all of the questions.

For this comparative study, we selected basic demographic and behavioural questions about wine consumption – questions which had been tested several times before (e.g. Hoffmann et al., 2006; Szolnoki et al., 2011; Szolnoki and Hoffmann, 2012). First of all, respondents were asked about the frequency of wine consumption through analysis of an image of wine, accompanied by seven statements. This was followed by questions about preferences related to origin, sweetness and wine type. Third, self-reports on levels of interest and knowledge about wine were requested. Finally, questions regarding sales channels used in wine purchasing were asked. The demographic data were collected at the end of the interviews. In the questionnaire, we used a seven-point interval scale (Friedman and Amoo, 1999) and constant sum scaling (Malhotra and Birks, 2007).

Taking the study of Duffy et al. (2005) as a basis, we were looking at differences between raw face-to-face, telephone and online data. Since the data from the first three studies were collected using quota sampling based on six demographic variables, we did not need to use weighting factors because the demographic pattern of the surveyed samples was identical to that of the official statistics. Even in the case of the snowball sampling, we did not use weighting, for the reason that a weighting factor greater than five is seen as very problematic (Bandilla et al., 2003).

4. RESULTS

First of all, the demographic data were analysed according to mode, as shown in Table 1. We used cross-tabulation and a chi-square test to analyse the differences. Because we wanted to investigate the discrepancies only between the national surveys done by external firms, the analyses were conducted first with all four modes, and second, only with the first three modes, excluding the online snowball sampling (signed in Table 1 with ‘a’). Since we used

¹ Since 2007, the Geisenheim University, Institute of Economics and Market Research, has been conducting, every second year, a representative face-to-face survey designed by the same research firm. A longitudinal estimate shows that the selected behavioural variables have not changed significantly within two years. Therefore, assuming that there are no significant differences between representative surveys within one year, we compared our two online studies and one telephone study conducted in 2012 with a face-to-face survey which was completed at the end of 2011.

quota sampling for the first three surveys, the discrepancies in basic demographic variables (gender, age, household size, city size, occupation, state) between the first three surveys and the micro-census statistics were only marginal. Therefore, we only outlined here gender, age and states, and then we concentrated later, on variables which were not part of the quota sampling.

Table 1 Demographic profile by modes

Characteristics (micro-census statistics)		Face-to-face n=2,068	Telephone n=1,000	Online quota n=2,000	Online snowball N=3,060	χ^2 /df	
<i>Gender %</i>							
Male	(49.0)	48.8	49.0	49.0	51.9	4.29	df=3

* $\chi^2 = p < 0.05$; a = χ^2 test conducted by excluding the snowball sampling data;

+ not completed; ++ completed after 9 years without baccalaureate; +++ completed after 10 years without baccalaureate.

In the online snowball study, the second youngest age group and the middle-west region are over-represented. This can be traced back to the fact that the invitation to participate in the survey was sent out by students from Geisenheim, who come mainly from the states Hessen and Rhineland-Palatinate (middle-west), and who apparently reached out to their friends from the same age group. As for the education level, we noticed significant differences even when snowball sampling was not included. Occupation of the interviewed persons was predefined; however, it does not correlate very highly with the education level. The telephone and online quota sampling contain many more interviewees with higher education than the face-to-face survey and, on the other hand, the least-educated individuals. The same pattern appears when comparing income per month. The online snowball sample with its higher part of young people studying at universities results in an over-represented high school – with baccalaureate and lower income category.

Table 2 summarises the behavioural variables for the four data sources, analysed with the help of cross-tabulation and a chi-square test or ANOVA using Tukey-B post hoc test. For some variables we displayed the results of a national representative survey (VA 2012 by Springer AG, 2012) conducted with 33,000 individuals and based on the micro-census statistics concerning the demographic variables. Unfortunately, VA 2012 statistics contain only three variables which could be compared with our samples. It should also be noted here, that the online snowball sample shows the largest discrepancies when compared with the other three surveys. However these variables also differ quite strongly among the face-to-face, telephone and online quota samples. With respect to consumption frequency, telephone and online quota data differ just marginally. Nevertheless, these surveys over-represent those consumers who drink wine very often and neglect the occasional wine drinkers. The face-to-face method clearly performs better than the other ones by accomplishing similar results to the VA 2012 statistics. The difference is visibly displayed in the case of per capita consumption.

Table 2 Wine consumption behaviour of the segments

Characteristics (VA 2012 statistics)	Face-to-face n=2.068	Telephone n=1.000	Online quota n=2.000	Online snowball N=3.100	χ^2 /df/ ANOVA
<i>Consumption frequency %</i>					
several times a week (10.0)	6.3	16.3	15.6	33.8	1323.97* df=15
once a week (7.8)	8.3	16.2	14.8	19.6	212.92a* df=10
2-3 times a month (14.5)	13.5	13.0	13.5	18.4	
once a month (8.2)	9.2	10.0	8.5	9.1	
rarer than once a month (23.9)	23.1	14.2	19.2	10.5	
never (35.6)	39.6	30.3	28.5	8.7	
<i>Preference of sweetness %</i>					
dry (29.3)	20.5	27.4	34.0	47.2	808.03* df=9
semi-dry (37.1)	51.1	37.3	42.4	22.7	81.73* df=6
semi-sweet/sweet (33.5)	28.4	35.3	23.6	30.1	
<i>Per capita consumption l</i>	34.8 ^a	54.1 ^b	50.5 ^b	68.7 ^c	**
<i>Preference of wine type %</i>					
White (44.9)	42.9 ^b	37.3 ^a	37.9 ^a	55.2 ^c	**
Rosé (10.0)	9.1 ^a	13.1 ^b	16.5 ^c	13.2 ^b	
Red (46.1)	47.9 ^{bc}	49.6 ^c	45.5 ^b	31.6 ^a	
<i>Preference of origin %</i>					
German wines	60.4 ^b	58.2 ^{ab}	57.4 ^a	69.3 ^c	**
Imported wines	39.6 ^b	41.8 ^{bc}	42.6 ^c	30.7 ^a	
<i>Involvement (scale -3 to +3)</i>					
Interest	-.84 ^a	.27 ^b	.46 ^c	.38 ^{bc}	**
Knowledge	-1.40 ^a	-.26 ^b	-.29 ^b	-.33 ^b	
<i>Use of sales channels %</i>					
Discount shop	35.9 ^a	29.7 ^b	30.3 ^b	16.0 ^c	**

Mail order/Internet	1.2 ^a	3.8 ^b	5.6 ^c	3.1 ^b	
Directly abroad	2.5	2.8	2.8	3.3	

* $\chi^2 = p < 0.05$; a = χ^2 test conducted by excluding the snowball sampling data; ** Tukey-B post hoc test, factor levels with different superscript are different at $p = 0.05$.

There are also highly significant differences in preferences regarding sweetness and in preferences regarding wine type. When analysing the preferences regarding sweetness, the telephone data fit much better with the VA 2012 statistics than the other three studies. The face-to-face survey over-represents the drinkers of semi-dry wines, while the online quota and

snowball sampling methods over-represent the dry wine drinkers. Concerning the preference for wine types, again, the face-to-face survey shows similarity with the VA 2012 statistics. The telephone and the online quota surveys reported a below-average preference for white wine, and the online snowball survey an above-average preference. In terms of preference for origin, there was an obvious difference between the data from the online snowball sample and data from the other surveys. Again, this might have occurred because of the way in which the students from Geisenheim recruited for the snowball sampling, as described above. The most conspicuous difference appears when comparing self-reported interest and knowledge about wine. Face-to-face surveys produced very low values, while the other three modes had significantly higher values. This means that highly involved individuals took part in the telephone surveys as well as the online quota surveys and the snowball surveys. The values of respondents in these three surveys do not differ significantly. We found, further, that there are significant differences in the use of sales channels when buying wine. The online snowball survey showed a bias towards buying wine at the winery, which was caused by the manner in which the recruiting for this survey was conducted. The results of this survey mode correlate strongly with the variables in terms of preference for origin, preference for wine type, preference for sweetness and consumption frequency. Among the three national surveys, results of the face-to-face method seem to be the most realistic in terms of sales channels usage. The greatest differences occurred in the references to discount shops and wine stores. The remaining sales channels are more or less on the same level. Finally, eight statements about wine were analysed according to survey mode. Generally, we can note that face-to-face interviewees evaluated all of the statements at a significantly lower level than the other respondents. We assumed that this result was closely related to the involvement of the individuals. In other words, low involvement with wine causes more negative attitudes and images associated with wine. For each statement there are significant differences; however, the largest contrast is found when wine is associated with its added value, as something suitable for special occasions, and ideal as a present. In addition, the taste of wine, and wine as an ideal supplement for a meal, were evaluated significantly lower by the face-to-face respondents than by the others (see Figure 1). The respondents in the online surveys returned the highest levels in these ratings, which, again, correlated highly with the level of involvement with wine.

5. SUMMARY AND MANAGERIAL IMPLICATIONS

This survey design made it possible to compare four modes. We analysed face-to-face, telephone and online panel surveys using quota sampling and an online survey with snowball sampling. Between the three surveys that used quota sampling, there were no substantial demographic differences, because they were conducted using six demographic variables as a basis. Nevertheless, the other demographic characteristics which were not included in the quota sampling caused significant differences. Also, this online-panel study has confirmed the fact that better educated people with higher incomes are strongly over-represented in online studies (cf. Hoogendorn and Daalmans, 2009). The uncontrolled online survey using snowball sampling showed a much more biased result towards youngsters with higher education and lower income, indicating that mainly friends of the students who sent out the questionnaire link participated in the survey.

The face-to-face survey delivered better results in terms of representativeness in the answers to questions about consumption frequency and preferences related to wine. However, the telephone survey was more representative concerning the preferences related to sweetness. Ethier et al. (2000) described different biases that can be defined due to the differences in survey mode. Social desirability bias occurs when individuals provide different responses in the presence of an interviewer so as to appear in a favourable light. This could be an issue in face-to-face or telephone interviews; however, we did not recognise this kind of bias in this study. Avidity bias means that those with a greater interest in the survey topic are more likely to respond. It means that people interested in the topic are more likely to participate than people without interest. This kind of bias probably appeared in both online surveys as well as in the telephone survey. As for the wine image statements, the face-to-face survey provided significantly lower values, which can be traced back to the lower involvement of the respondents, as reflected in their self-reporting.

In summarising the results of the study, we are not able to say which of the studies delivered clearly representative results without any kind of bias. Although the face-to-face survey performed better, even this sampling method had some weaknesses which resulted especially in the responses regarding involvement and the preferences in relation to sweetness. With respect to education, the face-to-face survey under-represents the individuals with university degrees. This became clear when the results were compared with the VA 2012 statistics; however, because of the difference in classification, only the last category (university) was comparable. The results of the telephone survey are similar to those of the online quota sampling method. These results differ in several points from the national representative survey. Nevertheless, it should be noted that the telephone survey was performed only with 1,000 respondents. The online survey conducted using snowball sampling delivered the most non-representative results. This is due to the uncontrolled situation and the special way of recruiting respondents. The Internet-based quota sample was more representative of the nation's population over 16 years than the snowball sampling was. The snowball sample was biased towards individuals who were highly knowledgeable about the survey topic and interested in it (cf. Chang and Krosnick, 2009). Couper (2011) warned, as a result of his study, that when comparing modes which are quite different – for example, telephone and online – there is an increased possibility of finding larger differences.

Furthermore, we should also take the cost of the surveys into account. The cost of data collection proved to be highest when using the face-to-face method and the lowest when using Internet quota sampling, whereas the telephone survey was somewhere in the middle in relation to cost. The online snowball sampling did not need extra budget funds; it required only time for programming the survey, sending the link and analysing the data.

This study has some limitations, such as the size and the timing of the different sampling methods. These should be considered and avoided, when the test will be repeated. On the

other hand, this study should be conducted also in other countries, to analyse the differences between the sampling methods on international level.

Finally, we can conclude that one should select very careful the sampling method depending on topic, goal and budget of the study. Face-to-face surveys still deliver the most representative results. However, even here, one should control the potential biases. Telephone surveys may provide a good alternative, but in this case, we would advise use of larger samples and integration of a stronger control to avoid biases. As we reported, it is possible to get an online survey using quota sampling which is representative of the selected demographic variables. Nevertheless, this sampling method needs much more correction or maybe some behavioural variables for the quota sampling. Therefore, this kind of sampling method is inadvisable, when it is about a representative study. The online survey with snowball sampling is, of course, not able to deliver representative results; but it can be easily used when we know the basic population and have online access to its members, or when we use a simple survey where no representativeness is required.
